Slogan (Bill Clinton): It depends on what the meaning of the word “is” is.

Our goal is to prove:

**Theorem 1.** Let \( n \geq 5 \). Let \( \Sigma^n \) be an exotic sphere and \( \Omega^n \) be an exotic torus, smooth manifolds which are homeomorphic, not diffeomorphic, to a sphere and torus respectively. Then \( T^n \# \Sigma^n \) is not diffeo to \( T^n \), and \( \Omega^n \times T^k \) is not diffeomorphic to \( T^{n+k} \).

1 Generalities

1. A *topological* \( n \)-manifold \( X \) is a second countable Hausdorff space locally homeomorphic to \( \mathbb{R}^k \).

2. A *smooth manifold* is a topological manifold with a maximal smooth atlas.

3. Let \( X \) be a topological \( n \)-manifold. A *smoothing of \( X \)* is a maximal smooth atlas on \( X \). A *marking on \( X \)* is a homeomorphism \( h : M \to X \) from a smooth manifold to \( X \); it induces a smoothing \( X_h \) on \( X \). Two markings \( h : M \to X \) and \( h' : M' \to X \) induce the same smoothing \( (X_h = X_{h'}) \) iff there is a diffeomorphism \( \phi : M \to M' \) so that \( h' \circ \phi = h \).

4. The *moduli set* \( M(X) \) is the set of diffeomorphism classes of smooth manifolds homeomorphic to \( X \).
5. Two smooth structures $X_0$ and $X_1$ on $X$ are *concordant* if there is a smooth structure on $X \times I$ which restricts to $X_i$ on $X \times i$, $i = 0, 1$. (A concordance is determined by a marking $H : W \to X \times I$).

6. Two smooth structures $X_0$ and $X_1$ are *isotopic* if there is a smooth manifold $M$ and a level-preserving homeomorphism $H : M \times I \to X \times I$ ($H(x, t) = (F(x, t), t)$) inducing $X_i$ on $X \times i$, $i = 0, 1$.

**Theorem 2** (Concordance implies isotopy). If $\dim X \geq 5$, then concordant structures are isotopic (and hence diffeomorphic).

Thus concordant structures are diffeomorphic. This also follows from the s-cobordism theorem.

7. The *structure set* $S(X)$ is the set of concordance classes of smoothing on $X$. Note

$$S(X) \hookrightarrow M(X)$$

**Example 3.** (a) A point has an infinite number of markings but one smoothing.

(b) $S^1$ has an infinite number of smoothings, but $S(S^1) = *$

(c) $S(S^7) = \mathbb{Z}/28$, $M(S^7) = \mathbb{Z}/28/(x \sim -x)$ so $\#M(S^7) = 15$

(d) $M(E_8^{1k}) = \emptyset$. ($E_8$ is a closed, topological manifold with signature 8, so that $E_8 - *$ is smoothable with a trivial tangent bundle.)

(e) Let $M$ and $N$ be a smooth manifolds with $\partial$ and $f : \partial M \to \partial N$ be a diffeomorphism. Then $M \cup_f N$ is a topological manifold. It doesn’t have a unique smoothing, but it has a unique concordance class of smoothings in $S(M \cup_f N)$.

Why is $S(X)$ nicer than $M(X)$? It is in bijection with a *computable* abelian group, and useful for gluing.

8. $\text{Homeo}(X) \curvearrowright S(X)$ $(\alpha, [X_h]) \mapsto [X_{\alpha h}]$. I.e. $M \xrightarrow{h} X \xrightarrow{\alpha} X$.

**Lemma 4.** $\text{Homeo}(X) \backslash S(X) \to M(X)$ is a bijection.

*Proof.* Well-defined and onto are clear.

Injective? If $f : M \to X, g : M \to X$ are markings, then $f = (f \circ g^{-1}) \circ g$. \qed
Let Homeo₀(\(X\)) be the group of homeomorphisms isotopic to the identity. The \textit{mapping class group} \(\text{MCG}(X)\) is \(\text{Homeo}(X)/\text{Homeo}_0(X)\). Two homeomorphisms \(\alpha, \beta \in \text{Homeo}(X)\) are \textit{pseudoisotopic} if there is \(\gamma \in \text{Homeo}(X \times I)\) so that \(\alpha = \gamma|_{X \times 0}\) and \(\beta = \gamma|_{X \times 1}\). The \textit{reduced mapping class group} \(\widetilde{\text{MCG}}(X)\) is \(\text{Homeo}(X)/\Psi\text{Homeo}_0(X)\), so two homeos represent the same element iff they are pseudoisotopic.

Note that \(\Psi\text{Homeo}_0(X)\) acts trivially on \(S(X)\). We conclude

\textbf{Lemma 5.} \(\widetilde{\text{MCG}}(X) \backslash S(X) \to M(X)\) is a bijection.

\textbf{Remark 6.} Suppose \(X_0\) is a smoothing of \(X\) and suppose \(\text{Diffeo}(X) \backslash S(X) \to M(X)\) is a bijection. Then any smoothing not concordant to \(X_0\) is not diffeomorphic to \(X_0\).

This is what happens for the torus.

\textbf{Lemma 7.} \(\widetilde{\text{MCG}}(T^n) \cong GL_n(\mathbb{Z})\)

\textit{Proof.} There is a split surjection \(H_1 : \text{Homeo}(T^n) \to GL_n(\mathbb{Z})\) split by \(L\). We need to show that any \(h : T^n \to T^n\) is \(\Psi\)-isotopic to \(L \circ H_1(h)\).

Note they are homotopic: (1) use \(T^n = K(\mathbb{Z}^n, 1)\) or (2) lift \(h\) to \(\tilde{h} : \mathbb{R}^n \to \mathbb{R}^n\). Take a straightline homotopy between \(\tilde{h}\) and \(L \circ H_1(h)\).

Now apply the Borel conjecture for \(T^n \times I\), to see the homotopy is homotopic, relative to \(\partial(T^n \times I)\) to a homeomorphism. \(\square\)

\section{Bundles}

Let \(BO(n) = \text{Gr}(n, \mathbb{R}^\infty)\). This is a \textit{classifying space for vector bundles over a finite CW complex} \(B\):

There is an \(n\)-plane bundle \(\gamma\) over \(BO\) so that

\[
[B, BO(n)] \to \{\text{iso classes of } n\text{-plane bundles over } B\}
\]

\[
[f] \mapsto [f^*\gamma]
\]

\textbf{Example 8.} Let \(M^n \subset \mathbb{R}^k\) be a smooth submanifold. Then \(M \to \text{Gr}(k, \mathbb{R}^n), \; p \mapsto T_pM \subset \mathbb{R}^n\).
Definition 9. Two vector bundles $\eta$ and $\xi$ over $B$ are stably equivalent if $\eta \oplus \mathbb{R}^k \cong \eta \oplus \mathbb{R}^l$.

Let $BO = \text{colim} BO(n)$. Then $[B, BO]$ classifies stable vector bundles over $B$. It is an abelian group, computable by the Atiyah-Hirzebruch spectral sequence.

Definition 10. A $n$-plane microbundle over $B$ is a pair of maps

$$B \xrightarrow{i} E \xrightarrow{p} B$$

satisfying $p \circ i = \text{Id}_B$ and the following local triviality condition: for every $b \in B$ there exists open neighborhoods $U$ of $b$ and $V$ of $i(b)$ with $i(U) \subset V$ and a homeomorphism $V \to U \times \mathbb{R}^n$ so that the following diagram commutes

\[
\begin{array}{ccc}
V & \xrightarrow{p} & U \\
\downarrow \cong & & \downarrow \cong \\
U & \xrightarrow{\text{Id} \times 0} & U \\
\end{array}
\]

Example 11. The tangent microbundle of a topological $n$-manifold $X$ is

$$X \xrightarrow{\Delta} X \times X \xrightarrow{p_1} X.$$
Most of the machinery of bundle theory applies to microbundles. For example, two bundles $B \xrightarrow{i} E \xrightarrow{p} B$ and $B \xrightarrow{i'} E' \xrightarrow{p'} B$ are isomorphic if there are neighborhoods $W$ and $W'$ of $i(B)$ and $i'(B)$ respectively and a commutative diagram

\[
\begin{array}{c}
W \\
\downarrow \\
\cong \\
\downarrow \\
W'
\end{array}
\begin{array}{c}
B \\
\cong \\
B
\end{array}
\]

An $\mathbb{R}^n$-bundle with a zero section is a fiber bundle $E \to B$ with fiber $\mathbb{R}^n$ and structure group $\text{TOP}(n) = \text{Homeo}(\mathbb{R}^n \text{ rel } 0)$. Every $\mathbb{R}^n$-bundle with a zero section determines a microbundle. A theorem of Kister and Mazur gives a one-to-one correspondence between isomorphism classes of $\mathbb{R}^n$-bundles with a zero section and isomorphism class of microbundles.

There are spaces $B\text{TOP}(n)$ and $B\text{TOP}$ which classify microbundles and stable microbundles. Assume $BO \to B\text{TOP}$ is a fibration by redefining $BO = E\text{TOP}/O$ or by replacing the map by a fibration.

### 3 Fundamental Theorem

Given a diagram

\[
\begin{array}{c}
B \\
\downarrow \\
A \xrightarrow{\alpha} C
\end{array}
\]

let $\text{Lift}_p(\alpha)$ be the set of maps $\hat{\alpha} : A \to B$ so that $p \circ \hat{\alpha} = \alpha$. Let $[\text{Lift}_p(\alpha)]$ be the set of vertical homotopy classes of lifts. A vertical homotopy is a map $H : A \times I \to B$ so that for all $a \in A$ and $t \in I$, $p(H(a, t)) = \alpha(a)$, in which case $H(\cdot, 0)$ and $H(\cdot, 1)$ are vertically homotopic. We will usually leave $p$ out of the notation.

**Fundamental Theorem of Smoothing.** Let $X$ be a topological manifold with $\text{dim } X \geq 5$. Let $\tau_X : X \to B\text{TOP}$ denote a classifying map of the stable tangent bundle. $X$ admits a smooth structure if and only if there is a lift
$X \to BO$ such that the following diagram commutes.

\[
\begin{array}{ccc}
  & BO \\
  \downarrow & \downarrow \\
X & \longrightarrow & BTOP \\
\end{array}
\]

In fact, the classifying map of the smooth tangent bundle gives a bijection

$S(X) \xrightarrow{\sim} [\text{Lift}(\tau_X)]$

where $[\text{Lift}(\tau_X)]$ denotes vertical homotopy classes of lifts of $\tau_X$ (vertical homotopy means a homotopy through lifts).

To illustrate some subtlety, note that exotic spheres are stably parallelizable – why does this not contradict the fundamental theorem?

### 4 Some homotopy theory

Let $X_h$ be smooth structure on $X$. We wish to establish a bijection

$j_h : [X, TOP/O] \xrightarrow{\cong} S(X)$

\[
\begin{array}{ccc}
TOP/O & \longrightarrow & BO \\
 \downarrow & \downarrow & \\
 & BTOP & \\
\end{array}
\]

1. $TOP/O$ is 2-connected (showing that it is path-connected is a difficult theorem - the solution to the annulus conjecture.)

2. $TOP/O, O, TOP, BTOP, BO$ are $H$-spaces (idea: $\mathbb{R}^\infty \oplus \mathbb{R}^\infty \cong \mathbb{R}^\infty$).

3. $TOP/O, O, TOP, BTOP, BO$ are infinite loop spaces: e.g. $\exists A_1, A_2, \ldots$ so that $TOP/O \cong \Omega A_1, A_1 \cong \Omega A_2, \text{ etc.}$, where $\cong$ means homotopy equivalent.

4. There is a long exact sequence of abelian groups

\[
\cdots \to [\Sigma B, BO] \to [\Sigma B, BTOP] \to [B, TOP/O] \to [B, BO] \to [B, BTOP]
\]

5. $BO \to BTOP$ is a principal $TOP/O$-bundle.
\textit{TOP/O} is an \(H\)-space and I am not going to spell out what I mean by a principal \(H\)-space bundle. But it does mean that there is a commutative diagram

\[
\begin{array}{ccc}
BO \times TOP/O & \longrightarrow & BO \\
\downarrow & & \downarrow \\
BTOP & &
\end{array}
\]

and hence a map \([B, BO] \times [B, TOP/O] \to [B, BO]\).

\textbf{Corollary 12.}

\[
\begin{array}{ccc}
BO & \downarrow \\
B \tau & \longrightarrow & BTOP
\end{array}
\]

The abelian group \([B, TOP/O]\) acts freely and transitively (on the right) on \([\text{Lift}(\tau)]\).

Thus if we choose a lift \(\tilde{\tau} : B \to BO\), there the orbit map gives a bijection \([B, TOP/O] \xrightarrow{\sim} [\text{Lift}\tau]\).

In particular, if \(M\) is a smooth manifold of dimension \(\geq 5\), there is a bijection

\[
j_h : [M, TOP/O] \xrightarrow{\sim} S(M)
\]

defined by acting on the tangent bundle \(\tau : M \to BO\) to get a new lift of \(p \circ \tau : M \to BTOP\), and choosing the corresponding smooth structure given by the fundamental theorem.

Furthermore, since \(TOP/O\) is an infinite loop space, the Atiyah-Hirzebruch spectral sequence applies to compute \([M, TOP/O]\), which is \(H^0\) of a generalized cohomology theory.

\section{5 Exotic spheres}

Let \(\Theta_n\) be the equivalence classes of smoothing on \(S^n\) under orientation-preserving diffeomorphism. This is an abelian monoid under connected sum.

\textbf{Lemma 13.} Let \(n \geq 5\).

1. \(\Theta_n\) is a finite abelian group.
2. \( S(S^n) \xrightarrow{\sim} \Theta_n \)

3. The composite \( \pi_n(TOP/O) \xrightarrow{\sim} [\text{Lift}(\tau S^n)] \xrightarrow{\sim} S(S^n) \xrightarrow{\sim} \Theta_n \) is an isomorphism of abelian groups.

Discussion of proof. Smale proved that every exotic sphere of dimension \( \geq 5 \) is obtained by gluing \( D^n \cup_f D^n \) for some diffeomorphism \( f : S^{n-1} \to S^{n-1} \). It follows that \( \Theta_n \) is a group. The finiteness is due to Kervaire-Milnor. It is easy to see an epimorphism \( S(S^n) \to \Theta_n \). To show injectivity one uses the Alexander trick.

\[ \square \]

**Lemma 14.** Let \( M \) and \( N \) be smooth manifolds with \( \dim M \geq 5 \).

1. If \( M \) is closed, connected, let \( c : M \to S^n \) be a degree one map; in general choose an embedded disk \( D^n \hookrightarrow M \) and let \( c : M \to M/(M - \text{int } D^n) = S^n \) be the quotient map. The following diagram commutes

\[
\begin{array}{ccc}
[S^n, TOP/O] & \xrightarrow{c^*} & [M, TOP/O] \\
\downarrow j & & \downarrow j \\
S(S^n) & \longrightarrow & S(M)
\end{array}
\]

where the bottom horizontal map is \([\Sigma] \mapsto [M\#\Sigma]\).

2. The following diagram commutes

\[
\begin{array}{ccc}
[M, TOP/O] & \xrightarrow{pr^*} & [M \times N, TOP/O] \\
\downarrow j & & \downarrow j \\
S(M) & \longrightarrow & S(M \times N)
\end{array}
\]

where the bottom horizontal map is \([M_h] \mapsto [M_h \times N]\).

**Proof.** 1. The idea is that there is a cobordism \( W \) from \( M \) to \( M \bigsqcup S^n \) and that the corresponding assertion is obvious for \( M \bigsqcup S^n \). Indeed, let \( \phi : S^0 \times D^n \hookrightarrow M \bigsqcup S^n \) (whose image intersects both \( M \) and \( S^n \)) and let \( W = (M \bigsqcup S^n) \times I \cup_\phi D^1 \times D^n \) be the result of adding a 1-handle to \( M \) along \( \phi \). Give \( W \) a smooth structure which restricts (up to concordance) to the given smooth structures on the boundary.
There is a commutative diagram

\[
\begin{array}{ccc}
[S^n, TOP, O] & \longrightarrow & [M \coprod S^n, TOP, O] \\
\downarrow j & \cong & \downarrow j \\
S(M \coprod S^n) & \cong & S(M) \\
\downarrow & \cong & \downarrow \\
S(S^n) & \longrightarrow & S(W) \\
\end{array}
\]

The middle and right horizontal arrows are induced by restriction, and the upper left horizontal arrow is induced by inclusion of a summand. For a smooth structure \(\Sigma\) on \(S^n\), let \(\alpha[\Sigma] = [M \coprod \Sigma]\) and \(\gamma[\Sigma] = [M \# \Sigma]\). For the definition of \(\beta\) choose a point \(p \in S^n\) and glue \(W\) minus an open tubular neighborhood of \(\{p\} \times I\) with \(\Sigma \times I\) minus an open tubular neighborhood of \(\{p\} \times I\). Note then that \(S(W) \rightarrow S(M \coprod S^n)\) is a bijection and Lemma 14 1 follows.

2. We will show that diagram below is commutative

\[
\begin{array}{ccc}
[M, TOP/O] & \longrightarrow & [M \times N, TOP/O] \\
\downarrow \cong & \downarrow \cong & \downarrow \cong \\
\text{[Lift } \tau_M\text{]} & \longrightarrow & \text{[Lift } \tau_{M \times N}\text{]} \\
\cong & \cong & \cong \\
S(M) & \longrightarrow & S(M \times N) \\
\end{array}
\]

where the middle horizontal arrow is defined using the \(H\)-space map \(BO \times BO \rightarrow BO\) which has that property that if \(X_i \rightarrow BO, i = 1, 2\) classifies a bundles \(\alpha_i, i = 1, 2\) then \(X_1 \times X_2 \rightarrow BO \times BO \rightarrow BO\) classifies \(\alpha_1 \times \alpha_2\). It follows that the bottom rectangle commutes. The top rectangle commutes because the following diagram commutes:

\[
\begin{array}{ccc}
BO \times TOP/O & \longrightarrow & BO \\
\downarrow & \cong & \downarrow \\
BO \times BO & \longrightarrow & BO \\
\end{array}
\]
6 The torus

Theorem 15. Let \( n \geq 5 \). Let \( \Sigma^n \) be an exotic sphere and let \( \Omega^n \) be an exotic torus.

1. \([T^n \# \Sigma^n] \neq [T^n] \in S(T^n)\)
2. \([T^k \times \Omega^n] \neq [T^{k+n}] \in S(T^{k+n})\).
3. \([T^n \# \Sigma^n] \neq [T^n] \in M(T^n) \) and \([T^k \times \Omega^n] \neq [T^{k+n}] \in M(T^{k+n})\).

Proof. 1. The key fact we need to show is that \( c^*: [T^n, \text{TOP/O}] \rightarrow [S^n, \text{TOP/O}] \) is injective. Since pr is split surjective, pr* is split injective, so the desired result follows from the above lemma. The key ingredients in showing that \( c^* \) is injective (actually split injective) are that \( \text{TOP/O} \) is 2-connected, that \( \text{TOP/O} \simeq \Omega A_1 \) for some space \( A_1 \), and that \( \Sigma T^n \simeq \vee e^j \).

We will also use the adjoint correspondence for based homotopy \([\Sigma X, Y], \simeq [X, \Omega Y], \) and that fact that for simply-connected targets, and path-connected domains, the forgetful map from based homotopy to unbased homotopy is a bijection.

Thus \( \Sigma c: \Sigma T^n \rightarrow \Sigma S^n \) has a homotopy right inverse, so \((\Sigma c)^*: [\Sigma T^n, A_1] \rightarrow [\Sigma S^n, A_1] \) is injective. Then, by applying the adjoint correspondence, \( c^* \) is injective.

2. This follows from Lemma 14 2.

3. This follows from 1. and the fact that \( \text{Diffeo}(T^n) \setminus T^n \cong M(T^n) \) which I proved earlier.

\( \square \)

In fact, the proof above shows

Theorem 16. For \( n \geq 5 \), \( M(T^n) \cong \oplus_i H^i(T^n, \pi_i(\text{TOP/O}))/\text{GL}_n(\mathbb{Z}) \).

The homotopy groups of \( \text{TOP/O} \) are listed below.

Remark 17. One can show that if \( X \) is a stably parallelizable manifold, that \( X \) and \( X \# \Sigma^n \) are not concordant. The idea is to use the Milnor-Spanier theorem and Spanier-Whitehead duality to show that \( X \) stably pinches off the top cell.
7 PL manifolds

Two definitions of PL-manifold

**Definition 18.** A *PL-manifold* is a topological manifold with a maximal PL-atlas.

**Definition 19.** A *PL-manifold* is a simplicial complex which is a topological manifold and with the link of every vertex a PL-disk.

The definition of $BPL(n)$ and $BPL$ are a little more complicated, since they are not topological groups. The definition of $PL/O$ is as the homotopy fiber of the map $BPL \to BO$.

Hirsch-Mazur show smoothing theory $PL/O$ works in every dimension, $PL/O$ is 6-connected.

Kirby-Siebenmann show smoothing theory $TOP/PL$ works in dimension $\geq 5$ and that $TOP/PL = K(\mathbb{Z}/2,3)$.

Thus

$$
\pi_i(TOP/O) = \begin{cases}
0 & i = 0, 1, 2, 4, 5, 6 \\
\mathbb{Z}/2 & i = 3 \\
\Theta_i & i \geq 6
\end{cases}
$$

Wall proves that $M(T^5)$ has three elements.

8 Nilmanifolds

Using that $\Theta_s$ is finite, on can prove

**Theorem 20.** Let $T^n_h$ be a smooth structure on a torus, $n \geq 5$. Then there is a finite cover diffeomorphic to the $T^n$.

**Theorem 21** (Davis). Let $X^n_h$ be a smoothing of a nilmanifold, $n \geq 5$. Then there is a finite cover diffeomorphic to a nilmanifold.

9 negatively curved manifolds

See my survey on Farrell-Jones.
